# Dynamics of the New American Majority, 2010-2030: 

 An Initial Look at Population Size, Growth, and Electoral ParticipationBernard L. Fraga, Ph.D. Zachary Peskowitz, Ph.D. Caitlin Gilbert, Ph.D.

Prepared for

The Voter Participation Center
Center for Voter Information

Draft as of April 19, 2022

## 1 Introduction and Background

The Voter Participation Center (VPC) and Center for Voter Information (CVI) focus on the mobilization of the New American Majority (NAM), a diverse multi-group coalition that is poised to drive U.S. politics for decades to come. However, efforts to mobilize this population are less effective in the absence of robust data on where NAM populations live now, where they will live in the future, and their relative rates of voting participation. In this report, we outline how we improve and expand upon VPC's existing understanding of NAM population dynamics to better inform both potential partners regarding opportunities for increased efforts and VPC/CVI's own program location decisions. Using a combination of U.S. Census Bureau products, individual-level Current Population Survey data, and comprehensive voter file data as provided by a voter file vendor, we identify areas of high NAM concentrations, high NAM population growth, and trends of interest in NAM subpopulation turnout rates.

In our report, we define the NAM as the aggregation of individuals with the following demographic characteristics:

- 18+ U.S. Citizen, AND
- Black, AAPI, AIAN, Multiracial, OR
- Hispanic (any race), OR
- Under 35, OR
- Unmarried Woman

The population that does not qualify as part of the New American Majority, or non-NAM, was defined as the voting-eligible complement of the NAM, that is:

- 18+ U.S. Citizen, AND
- Non-Hispanic White alone Men 35+, OR
- Non-Hispanic White alone Women 35+ who are married

### 1.1 Existing Forecasts of the NAM Population

The New American Majority (NAM) population, in whole or in part, is of interest to demographers and civic engagement organizations alike. For example, in the enumerated mandate of the Center for American Progress, American Enterprise Institute, and Brookings Institution's "States of Change: Demographics and Democracy" project, the first goal is to "document and analyze the challenges to democracy posed by the rapid demographic evolution from the 1970s to 2060." ${ }^{1}$ The initial (2015) States of Change report offers a thorough analysis of both national and state-level trends for NAM populations. This includes projections of the total population and voting eligible (i.e., citizen) population by race/ethnicity, age, and marital status (along with college vs. non-college) at the state and national level to 2060. While useful, the intersections of these demographic factors are not explored in great enough detail to project the aggregate NAM population (as defined above). Thus, while widely used, ${ }^{2}$ and updated in $2020,{ }^{3}$ this report on its own is not sufficient for understanding current and future NAM population trends.

Going below the state level, recent work estimates the county-level population by race, age, and gender to $2100 .{ }^{4}$ Again, this analysis is insightful, but does not provide information on Asian Americans, marital status, or citizenship rates, and is highly dependent on assumptions regarding climate change mitigation to avoid a large overestimation of the total population.

Finally, the U.S. Census Bureau itself produces projections of the population beyond the current year at the national level. This includes breakdowns by age group, sex, race/ethnicity, and nativity (i.e., foreign vs. native-born populations) to $2060 .{ }^{5}$ However, the Census Bureau

[^0]no longer produces population projections at the sub-national level, with the final state-level demographic projections produced in 1997.

### 1.2 Existing Analyses of NAM Voter Turnout

Voter turnout for NAM populations receives similar attention, though with greater constraints in data availability. The Census Bureau and Bureau of Labor Statistics collaborate to produce and administer the Current Population Survey Voting and Registration Supplement (CPS), which includes information on race/ethnicity, age, gender, marital status, and whether or not the respondent voted in the most recent election. The Census Bureau produces reports in the spring following each federal election year summarizing the survey's findings for major demographic categories, in particular, race/ethnicity ${ }^{6}$. While turnout for the NAM is not explicitly estimated in CPS reports, individual-level responses to the CPS are public and can be used to construct turnout rates by NAM/Non-NAM status as we discuss in the report.

The Current Population Survey informs much of our understanding of demographic differences in voter turnout. Indeed, CPS turnout estimates have been viewed as authoritative information for academics regarding racial/ethnic differences in voter turnout, ${ }^{7}$ at least going back in time. ${ }^{8}$ The Supreme Court also relied on CPS data to validate their assertion that "things have changed in the South" and that Section 4's Voting Rights Act preclearance coverage formula was no longer constitutional (Shelby County v. Holder, 2013). However, since the CPS is a survey (albeit a very large one), the possibility of bias due to differential non-response has increased, ${ }^{9}$ and recent work indicates that racial/ethnic differences in overreporting of turnout undermine the use of the CPS for measuring racial/ethnic differences

[^1]in turnout like those cited in the Shelby decision. ${ }^{10}$ Furthermore, and despite the relatively large sample size, published margins of error on turnout rates are very large for demographic intersections and most states. ${ }^{11}$

While the candidate an individual chooses is private, information about whether or not an individual voted is generally publicly available. As discussed in Eitan Hersh's 2015 book Hacking the Electorate: How Campaigns Perceive Voters, ${ }^{12}$ candidates for public office have long used voter registration lists (or "voter files") as their primary source of information for identifying and mobilizing potential supporters. A recent resurgence in targeted GOTV operations, along with improvements in computing power, means that both partisan and non-partisan data aggregators work to compile national lists of all registered voters and their turnout behavior. Importantly, though, demographic data on registrants is limited to either information requested on voter registration forms (including name, sex/gender, date of birth, and address), or traits that can be modeled using this information (including race/ethnicity ${ }^{13}$ and marital status).

Voter file aggregators have conducted analyses of turnout rates for NAM subpopulations as well. A prominent example is the "What Happened?" project by Catalist, LLC. ${ }^{14}$ Using a combination of proprietary voter file-based modeling, analysis of Census demographics, and inferences regarding subgroup behavior based on the aforementioned CPS, they provide estimates of turnout and shares of the electorate by race/ethnicity, gender, and educational status. We use data from a voter file vendor to measure NAM subgroup behavior.

[^2]
### 1.3 Key Findings

In this report, we focus on understanding the size and electoral participation of the citizen voting-age New American Majority (NAM) population. ${ }^{15}$ We rely on a combination of aggregate U.S. Census Bureau, individual-level CPS, and individual-level voter file data to provide an intial look at how the size and distribution of the NAM has changed over the previous decade (2010-2020), how it is poised to change over the next decade (20202030), and the registration and turnout rates of the NAM in the most recent midterm and presidential elections.

The data we have compiled indicates the following:

- The New American Majority population is predicted to make up a 2 percentage point larger share of the total voting-eligible population in 2030 than it did in 2020.
- $55 \%$ of the NAM today are People of Color, but we see significant geographic variation in the NAM share that is POC by state and by county within state.
- NAM growth from 2010-2030 is projected to be especially strong in New England states, and weaker than the national average in the South \& Midwest
- Trends in voter turnout for young people and racial/ethnic minority groups do not indicate a closing of longstanding disparities, with the exception of Asian American turnout which surged in the 2020 election.
- We see no significant change in relative turnout by unmarried women versus married women from 2012-2020, but turnout for both groups is much closer than for married versus unmarried men based on CPS survey data.

[^3]- Voter file data likely provides more accurate estimates of turnout for the NAM and most NAM subgroups at the national level than CPS survey data, and provides the only suitable estimates of sub-state and intersectional turnout rates for these and other populations.
- Estimates of the unregistered voter population are highly contingent on difficult-toquantify state variation in list maintenance procedures ("voter purging"), but there are at least 19 million NAM adult citizens who did not vote in 2020 and likely needed to update their registration or register to vote for the first time.

## 2 Data Sources

### 2.1 Population Estimates Program (PEP)

Our principal source of information about the NAM comes from the U.S. Census Bureau's Population Estimates Program (PEP). ${ }^{16}$ The PEP provides yearly estimates of the U.S. resident population by incorporating administrative records on deaths, births, and (im)migration to project the population based on the most recent decennial census. ${ }^{17}$ Publicly available PEP data includes estimates of the population by age, sex, and race/ethnicity for the nation, states, counties, and large municipalities. Today, the PEP is the primary reference for estimating the adult population in annual or sub-annual Census products, including the American Communities Survey and Current Population Survey. Estimates of the size of the voting eligible population often rely on the PEP, though augmenting these estimates with citizenship information not estimated by the PEP. ${ }^{18}$

The PEP publishes updated estimates of the population from the most recent past Census

[^4]to the preceding year, updating previous estimates with each new vintage. In this report, we rely on the Vintage 2020 data, which was released in the summer of 2021 and estimates the population from July 2010 to July 2020. The PEP uses a yearly additive cohort-component model, whereby yearly administrative records regarding births, deaths, international migration, and domestic migration by age, sex, and race/ethnicity are combined with baseline 2010 Census data to produce estimates of the population for a given postcensal year. We interpolate or extrapolate these modeled annual estimates to November of each year. ${ }^{19}$ More information about our procedure for compiling PEP data may be found in the Technical Appendix.

### 2.2 American Communities Survey (ACS)

The PEP provides estimates of the voting-age population by sex, race/ethnicity, and age, but leaves out two key demographic factors necessary to quantify the NAM. To acquire information regarding citizenship and marital status by sex, age, and race/ethnicity, we rely on the American Communities Survey (ACS), a U.S. Census Bureau product that is the result of a large-scale household-level stratified random sample. ${ }^{20}$. The ACS replaced the "long form" version of the Census that was given to a sample of the enumerated population every 10 years prior to 2010. Importantly, the ACS asks a series of questions regarding individual demographics of all household members, including citizenship status and marital status. ACS citizenship estimates play a dominant role here, as the Census provides estimates of how many persons are citizens by age, race/ethnicity, and sex at the national, state, and substate level in their ACS 5-year tabulations. To calculate the citizen voting-age population of unmarried women, we adjust the counts for women citizens (by race/ethnicity and age where appropriate) for each geography by averaging the white female unmarried rate from

[^5]the average of the three most recent respondent-level ACS 5-Year Public Use Microdata Samples (PUMS). More information about our procedure for compiling ACS data may be found in the Technical Appendix.

### 2.3 Current Population Survey (CPS)

Since 1964, the U.S. Census Bureau and Bureau of Labor Statistics have collaborated to produce and administer the Current Population Survey Voting and Registration Supplement (CPS), a biannual survey of over 55,000 households that is part of the broader, monthly survey series used to estimate adult labor force characteristics. ${ }^{21}$. The CPS sampling frame currently includes all civilian adults in noninstitutional housing, ${ }^{22}$ and queries respondents regarding the voter turnout, voter registration, methods of voting, and reasons for nonparticipation of household members. Beyond the sample size and time series, the major useful feature of the CPS is the inclusion of a number of standard demographic characteristics, including self-reported race/ethnicity, age, gender, and marital status. In addition to public reports, the Census Bureau produces a series of tables estimating turnout by age, race, and sex at the state level. ${ }^{23}$

The Census Bureau also makes public individual-level data from the CPS, which we use to construct turnout rates by NAM/Non-NAM status. Consisting of approximately 140,000 observations, the public datasets represent the result of a monthly (in this case, November) multi-wave household- based stratified sampling scheme. While the Census Bureau does provide margins of error using generalized variance parameters for statistics in their reports, they do not make publicly accessible information about the sampling scheme required to validate these estimates or construct estimates for all subpopulations (e.g., the NAM population). We follow the procedure outlined by former Census Bureau researchers including

[^6]Michael Davern, ${ }^{24}$ as implemented in recent political science work ${ }^{25}$ to approximate the sampling scheme using respondent geographic indicators, and compute $95 \%$ confidence intervals for CPS rates of voter turnout.

### 2.4 Voter File Data

As noted above, surveys examining voter turnout have been important in political science work, but practicioners tend to rely on voter file data. Recent research indicates that this decision is warranted: the CPS systematically overestimates minority voter turnout to a degree greater than for non-Hispanic White voter turnout. ${ }^{26}$ As a result, we also rely on individual-level voter turnout records from a data vendor specializing in voter file aggregation and demographic modeling. The vendor provided information on each individual they recorded as having voted in the 2018 and 2020 elections, including gender, age, geolocation, and modeled race/ethnicity. We aggregate these individual-level datapoints to our geographic units of interest. To accommodate potential error in race/ethnicity modeling, we rely on summing the probabilistic model scores instead of categorical indicators, a standard practice in the emerging literature on race modeling procedures. ${ }^{27}$ This provides estimates of the modeled number of non-Hispanic White, non-Hispanic Black, Hispanic/Latinx, and non-Hispanic Asian American or Pacific Islander populations.

We also rely on the voter file vendor's coding of voter registration status as of November 2020. For individuals marked as having voted in the 2020 election, we assume that they were registered to vote. As noted by previous scholars, states vary in their list maintenance procedures to a large degree, such that estimating differences between the size of the registered and

[^7]unregistered populations across states or for subgroups is necessarily tentative. ${ }^{28}$ In some states, the number of registered voters mistakenly appears to exceed the number of votingage citizens. However, we provide these estimates to suggest the geographic distribution of unregistered NAM adults with the best available administrative data.

## 3 NAM Population Size and Population Forecasts

We use the Census Bureau data discussed above to estimate both the NAM and NAM subgroup populations from 2010 to 2030. Since our interest is in making relatively shortterm projections, we rely on the assumption that the trends witnessed over the past decade will carry forward over the next decade. Specifically, we model change in the population size for each NAM constituent group from 2020-2030 as a function of the change in the NAM constituent group population from 2010-2020, as estimated by the U.S. Census Bureau. ${ }^{29}$

We use an exponential smoothing state space model to make forecasting projections for 2020-2030. We assume an additive error and trend structure with no seasonality. We implement the forecasting in $\mathbf{R}$ using the forecast package. ${ }^{30}$ The count of each demographic subgroup in each geography is forecast separately and then aggregated to the geography level to construct a forecast of the total citizen voting-age population. As an alternative robustness approach, we also generated forecasts of the total citizen voting age population for each geography. The resulting state-level citizen voting-age population forecasts exhibit a correlation greater than 0.999 with one another. The correlation is similarly high at the county-level.

[^8]
### 3.1 National

In Table 1 we report our national-level estimates and forecasts of the citizen NAM share of the citizen voting-age population (CVAP) in November 2010, November 2020, and November 2030. For the forecasts in November 2020 and November 2030 we provide 95 percent forecast error lower and upper bounds. The NAM has grown substantially from 2010 to 2020 and our forecasting results anticipate that this will continue over the next decade. In the final column we report the estimate and forecasts in the share of the NAM population that consists of persons of color (i.e., persons who are not non-Hispanic White race alone). Examining this column we see that at the same time the NAM has increased, the proportion of the NAM that is made up of people of color has increased at an even faster rate. Thus, at the national level, the growing NAM share overall is largely a function of the growing POC population relative to other non-POC NAM groups.

Table 1: U.S. New American Majority (NAM) Population Share, 2010-2030

|  | NAM Share | $95 \%$ FE LB | $95 \%$ FE UB | POC \% of NAM |
| ---: | ---: | ---: | ---: | ---: |
| 2010 | 0.570 |  |  | 0.493 |
| 2020 | 0.614 | 0.596 | 0.631 | 0.555 |
| 2030 | 0.634 | 0.592 | 0.676 | 0.603 |

### 3.2 State

In Table 2 we report the top 10 and bottom 10 states by NAM share of the citizen voting-age population in November 2010. The second column reports the ratio of citizens in NAM groups and the state CVAP. Hawaii had the highest share NAM population among all states in 2010 while New Hampshire had the lowest share. Slow-growing states with a larger rural population in the Northeast and West tend to have lower NAM shares. The third column reports the share of the state's NAM that are people of color. There is enormous heterogeneity across states in the share of the NAM population that consists of persons of color. Persons of color tend to compose a larger share of the NAM population in States with
large NAM population shares. The fourth column reports the total CVAP in each state in 2010.

Table 2: Nov. 2010 NAM Population for States

| State | NAM \% | POC \% of NAM | CVAP |
| :--- | ---: | ---: | ---: |
| Top 10 |  |  |  |
| HI | 0.847 | 0.864 | 969,086 |
| DC | 0.835 | 0.716 | 461,613 |
| NM | 0.700 | 0.737 | $1,430,586$ |
| CA | 0.676 | 0.711 | $23,163,812$ |
| TX | 0.647 | 0.674 | $15,986,660$ |
| MS | 0.638 | 0.599 | $2,184,704$ |
| LA | 0.636 | 0.561 | $3,343,977$ |
| MD | 0.624 | 0.614 | $4,063,998$ |
| GA | 0.622 | 0.600 | $6,727,350$ |
| NY | 0.611 | 0.546 | $13,220,203$ |
| Bottom |  |  |  |
| NE | 0.477 | 0.235 | $1,313,413$ |
| ID | 0.473 | 0.209 | $1,094,169$ |
| WI | 0.469 | 0.246 | $4,228,980$ |
| MN | 0.466 | 0.226 | $3,861,069$ |
| MT | 0.465 | 0.212 | 762,041 |
| IA | 0.453 | 0.146 | $2,254,813$ |
| WV | 0.452 | 0.123 | $1,456,776$ |
| VT | 0.440 | 0.093 | 489,304 |
| ME | 0.425 | 0.088 | $1,039,033$ |
| NH | 0.423 | 0.114 | $1,004,009$ |

In Table 3 we report forecasts for NAM shares in November 2020. The figure layout is identical to the previous table except with the addition of a 95 percent forecast error lower bound in column 3 and a 95 percent forecast error upper bound in 2020. These forecast errors account for estimation error from extrapolating out Census population estimates from July 2020 to November 2020. The NAM share of the CVAP increased in all states except for Arkansas from 2010 to 2020.

In Table 4, we report the forecasts for 2030. The uncertainty intervals around the forecast point estimates are significantly larger than for the 2020 forecasts. With the important exceptions of Arkansas and Alabama, given their already relatively large NAM populations,

Table 3: Nov. 2020 NAM Population for States

| State | NAM $\%$ | $95 \%$ FE LB | $95 \%$ FE UB | POC $\%$ of NAM | CVAP |
| :--- | ---: | ---: | ---: | ---: | ---: |
| Top 10 |  |  |  |  |  |
| HI | 0.855 | 0.818 | 0.892 | 0.879 | $1,029,717$ |

| ME | 0.434 | 0.423 | 0.446 | 0.118 | $1,089,886$ |

the NAM share is forecasted to increase in all states from 2010 to 2030.
In Table 5 we report the 10 states with the highest growing NAM share between 2010 and 2030 based on our forecasting exercise. The second and third columns report the NAM share in 2010 and 2030 respectively and the fourth column reports the growth rate of this share. The fifth column reports the forecasted change in the count of NAM citizens from 2010 to 2030. California, Texas, and Florida have the highest growth in the number of NAM citizens.

| TX | 0.647 | 0.745 | 0.151 | $6,109,259$ |
| CA | 0.676 | 0.777 | 0.149 | $6,861,677$ |
| MA | 0.517 | 0.589 | 0.139 | 894,249 |
| AZ | 0.574 | 0.646 | 0.125 | $1,474,661$ |
| MD | 0.624 | 0.701 | 0.123 | 781,663 |

### 3.3 County

In Table 6 we report the top 10 and bottom 10 counties by citizen NAM share of the CVAP in November 2010. In all of our county level results, we restrict attention to counties with more than 50,000 residents in 2010 to ensure we are focusing on electorally-important counties and counties where population projections are likely to be more accurate. The fourth column reports the NAM share, the fifth column the person of color share of the NAM population, and the sixth column the count of the CVAP. Most of the top 10 NAM counties are located in large metropolitan areas. The largest city and county seat of Dougherty County, Georgia is Albany, Georgia and the county has a large Black population. Imperial County, California is a largely rural county with a large Latino population. The lowest NAM counties are concentrated in the Midwest and Northeast. Sumter County, Florida is famously the location of The Villages retirement community that has been the site of multiple Republican presidential candidate visits.

Table 6: Nov. 2010 NAM Population For Counties > 50,000 Total Population

| County | State | FIPS | NAM $\%$ | POC $\%$ of NAM | CVAP |

In Table 7 we report our NAM forecasts for Nov. 2020. The format is identical to the prior table with the addition of measures of forecast error uncertainty in the fifth and sixth columns. Counties in Texas' Rio Grande Valley, such as Cameron and Hidalgo counties, experienced large NAM increases relative to 2010.

In Table 8 we report our NAM forecasts for Nov. 2030. Clayton County, Georgia located in the Atlanta metropolitan area is projected to have the highest NAM share of any county (among those with over 50,000 residents in 2010) in the United States.

In Table 9 we use our forecasts to report the top 10 fastest growing NAM counties from 2010 to 2030. Counties located in suburban and exurban areas of large metropolitan areas, such as Atlanta, Dallas, and New York, are projected to have some of the largest NAM increases in the country by 2030.

## 4 NAM Voter Turnout Rates

### 4.1 Current Population Survey-based estimates, 2012-2020

Figure 1 presents estimates of NAM and non-NAM turnout by election year. The Black intervals at the top and bottom of each bar indicate a $95 \%$ confidence interval on the estimates, which is relatively small compared to the much larger disparities between midterm and presidential elections. Consistent with prior studies, the NAM population votes at substantially lower rates than the non-NAM population, across election cycles, and with relatively little change in the gap within election type over time. In 2020, for example, the NAM turnout rate was $61 \%$ according to the CPS, while the non-NAM turnout rate was $75 \%$.

Figure 1: CPS Turnout for NAM vs. Non-NAM CVAP

Figure 2: CPS Turnout for POC vs. non-Hispanic Whites

Figure 2 presents estimates of turnout for People of Color and non-Hispanic Whites alone. Again consistent with prior work, and with the NAM/non-NAM estimates in Figure 1, people of color display significantly lower turnout according to the CPS. However, here we see more variation in the size of the gap. The CPS reports that the smallest (though still significant) gap in turnout between 2012 and 2020 was in the 2012 election, roughly 6 percentage points. Largely because of high Black voter turnout, this election stands in stark contrast to more recent trends where high turnout overall did not reduce turnout disparities.

While national-level CPS statistics with binary classifications imply relatively little random survey error, uncertainty in turnout estimates is more substantial for smaller subgroups. For instance, in Figure 3, we break down turnout by race/ethnicity for individuals 18-34 using CPS data. The $95 \%$ confidence intervals on the turnout estimates are large enough here that it is difficult to make firm conclusions regarding change in turnout over time in pres-

Figure 3: CPS Turnout by Race/Ethnicity, 18-34 year olds only

idential elections for most racial/ethnic groups, or differences within a single election year across some racial/ethnic groups. While it looks like turnout for non-Hispanic whites under 35 was higher than for AAPI young adults in 2020, uncertainty is high enough that this could be due to sampling error. Similarly, the confidence intervals on AAPI turnout are too large with CPS data to make firm conclusions regarding a significant increase between the 2016 and 2020 elections.

A breakdown by gender and marital status again demonstrates a limitation of the CPS data. Figure 4 presents turnout for 35 and older married women, unmarried women, married men, and unmarried men. Overall, married individuals are more likely to vote than unmar-

Figure 4: CPS Turnout by Gender and Marital Status, $35+$ Only

> Turnout rate for all over- 35 year-olds by gender/marital status

ried persons, ignoring gender. However, in several recent presidential elections married men and women vote at almost exactly the same rate according to the CPS. Unmarried women also appear to vote more than unmarried men across recent elections. Yet, while the unmarried gender gap has not changed substantially in presidential years from 2012 to 2020, the difference in turnout between unmarried men and women is no longer statistically significant in 2020.

### 4.2 Voter File-based estimates, 2012-2020

Turning to Voter File-based estimates of voter turnout rates, we see a more detailed portrait of political participation for key NAM subgroups. Table 10 presents the turnout rate (number of voters divided by the CVAP) for elections from 2012-2020 broken down by race/ethnicity, gender, and age group.

Table 10: Census + Voter File-based Turnout Rate Estimates, 2012-2020

|  | $\mathbf{2 0 1 2}$ | $\mathbf{2 0 1 4}$ | $\mathbf{2 0 1 6}$ | $\mathbf{2 0 1 8}$ | $\mathbf{2 0 2 0}$ |
| :--- | ---: | ---: | ---: | ---: | ---: |
| Total | 57.5 | 37.2 | 59.5 | 51.3 | 67.7 |
| POC | 45.5 | 24.0 | 44.1 | 36.4 | 50.7 |
| Non-POC | 61.8 | 43.5 | 67.7 | 59.5 | 77.5 |
| Women | 59.8 | 38.0 | 62.8 | 53.5 | 70.3 |
| Men | 55.0 | 36.3 | 56.1 | 49.0 | 64.9 |
| White | 61.8 | 43.5 | 67.7 | 59.5 | 77.5 |
| Black | 54.4 | 29.3 | 48.3 | 40.4 | 52.5 |
| Hispanic | 35.8 | 17.0 | 37.3 | 29.9 | 43.7 |
| AAPI | 42.1 | 23.7 | 46.6 | 39.7 | 60.5 |
| 18-24 | 30.3 | 10.0 | 34.0 | 22.5 | 45.2 |
| 25-34 | 42.6 | 18.6 | 45.2 | 33.9 | 52.9 |
| 35-44 | 53.9 | 29.4 | 55.6 | 44.9 | 64.3 |
| 45-54 | 63.5 | 40.6 | 64.9 | 53.2 | 69.9 |
| 55-64 | 71.4 | 52.6 | 72.3 | 64.2 | 75.8 |
| $65+$ | 71.8 | 59.5 | 74.1 | 73.9 | 84.2 |

Similar to both published CPS estimates and Figures 1-4 in the previous section, Table 10 indicates many substantial disparities in rates of turnout between NAM groups and nonNAM groups. Overall, the combination of Census CVAP estimates and the voter file vendor's records produces an estimate of Total turnout in the 2018 election (51.3\%) that is quite close to the leading estimate of actual turnout of voting-eligible persons, as produced by Michael McDonald (50.0\%). ${ }^{31}$. For 2020, the figure for the turnout rate of all voting-age citizens ( $67.7 \%$ ) is strikingly similar to the $66.8 \%$ turnout rate estimated by McDonald. ${ }^{32}$ Yet we see a gap between POC and non-POC turnout that is approximately twice as larger as what is

[^9]found in the CPS in 2018, with POC turnout 12.5 percentage points below non-POC turnout in this midterm election. In 2020, the difference between voter file-based estimates and the CPS is even larger, at 17 percentage points. With voter file data, we also see that turnout for 18-34 year olds is less than half that of those 55 and older, with less than a quarter of 18-24 year olds turning out to vote versus somewhat higher estimates in the CPS.

Table 10 indicates that these trends are longstanding, but turnout rates have shifted more for some groups than for others. 2018 and 2020 saw record levels of turnout for midterm and presidential elections, respectively. Across all groups we saw an increase in turnout relative to 2014 and 2016. However, Black and Hispanic turnout increased significantly less (approximately 4 and 6 percentage points) than for other racial/ethnic groups from 20162020, and while youth turnout surged 18-24 year old turnout still lagged behind voting rates for all other age groups. That said, we do see some indications of the gap between youth turnout and turnout of older individuals being smaller than in 2018, and AAPI turnout rates increased more than for any other racial/ethnic group in both the 2018 midterm (relative to 2014) and 2020 presidential (relative to 2016) elections.

Table 11 provides a more detailed breakdown of turnout by age group and race, disaggregating national turnout data with more precision than would be possible with CPS data alone (see Figure 3.) The table makes it clear that the aforementioned increase in youth turnout was also a story about racial/ethnic group differences. AAPI and White 18-24 year olds saw large increases in turnout rates in 2020 relative to 2016, including an over 20 percentage point increase for the youngest group of AAPIs. However, AAPI turnout grew dramatically across age groups as well, complicating a story about age in isolation. Similarly, while turnout for Black 18-24 year olds lagged behind every other racial/ethnic group, Black turnout also saw relatively small increases in all age categories except for those 65 or older. In every age category, as in every election examined here, White turnout rates were higher than Black, Latinx, and AAPI turnout rates.

These national trends present a picture of NAM subgroup voter turnout that can be

Table 11: Voter File-based Turnout Rate Estimates, Age x Race, 2012-2020

|  | $\mathbf{2 0 1 2}$ | $\mathbf{2 0 1 4}$ | $\mathbf{2 0 1 6}$ | $\mathbf{2 0 1 8}$ | $\mathbf{2 0 2 0}$ |

| Hispanic | 67.4 | 46.0 | 65.7 | 60.5 | 71.7 |
| White | 75.2 | 66.8 | 79.5 | 81.1 | 89.7 |

further enhanced by examining state trends. In Table 12, we present a sampling of 2020 turnout data for core NAM groups at the state level. We identify the five states with the greatest (positive) difference from the turnout rate for Whites (compared to POC, Black, Hispanic, and AAPI turnout) and adults 35 or older (compared to 18-24 and 25-34 year
olds). ${ }^{33}$

With regard to voters of color, several southern states stand out as driving high POC

[^10]turnout in Table 12. North Carolina and Florida see the highest rates of POC turnout on average, driven by relatively high turnout among Black voters North Carolina and Black and Hispanic voters in Florida. However, some of this has to do with relatively high rates of turnout overall. Relative to Whites, Alabama and South Carolina have the smallest disparities between POC and White or Black and White turnout rates.

Geographic variation in turnout rates by age are particularly striking. Though missing age data accounts for some of the high variance, in Nevada nearly two-thirds of adult citizens under 25 turned out to vote, while less than half did nationwide. High turnout overall can account for some of this story. Relative to the over 35 year old turnout rate, California and New Jersey instead make appearances as states with the smallest (though still large at 10-15 percentage points) disparities between youth and non-youth turnout rates.

### 4.3 Discrepancies between CPS and Voter File-based Estimates

In this section, we take a closer look at discrepancies between the CPS-based estimates of turnout for NAM groups and the estimates derived from the voter file vendor. Tables 13 and 14 present national estimates of turnout in the CPS and voter file, the $95 \%$ confidence interval for the CPS estimate, and an indicator $\left({ }^{*}\right)$ for significant differences assuming no survey error for the voter file quantities.

In both years, we see significant differences in turnout rates between the two datasets for nearly all of the NAM (and non-NAM) constituent demographic categories. For the most part, the CPS seems to slightly overestimate turnout rates. Some of the discrepancies between the CPS and voter file-based analyses may thus stem from the target population in the CPS sample. For instance, the CPS appears to consistently underestimate the size of the NAM CVAP population, which would produce higher rates of turnout even if the number of voters stayed constant. In 2020, this undercount was approximately 7 million persons, and while the non-NAM is also undercounted, the disparities are not proportionate. About half of the NAM undercount is due to the fact that the CPS excludes college students in dorms

(since 2018) and people who are incarcerated, even if they are eligible to vote. Nursing home residents are also excluded, although this population skews non-NAM and would produce a
countervailing bias.
However, in general discrepancies between the CPS and voter file are clearest when studying communities of color. In recent work, Ansolabehere, Fraga, and Schaffner (2021) ${ }^{34}$ demonstrate that the CPS systematically overestimates minority voter turnout, even after accounting for the aforementioned differences in sample composition and random survey error. This study also isolates states in the south where race is on the voter registration list, so modeling challenges cannot account for all of the discrepancies. We see a similar pattern in our comparison, whereby minority turnout is systematically higher at the national and state level in the CPS, relative to the voter file, in most states and for most groups.

## 5 Unregistered NAM Population

As a final study, we also sought to use the voter file vendor data to study the unregistered NAM population, with an eye toward identifying states with relatively large unregistered NAM adult populations. In Tables 15 and 16 we present the top 10 states in terms of the percent of unregistered adult citizens who are POC, and the raw number of unregistered POC adult citizens, respectively. Texas, Louisiana, and Arizona are the only states to make both lists, with large absolute and relative numbers of potential NAM voters who were unable to vote as of November 2020. A full table examining the unregistered Total and POC population in every state may be found in Table 19 in the Appendix.

Table 17 identifies where low registration rates are having an especially large impact on the underrepresentation of people of color. Here we present the raw number of voting-age citizens and active registered voters who are people of color in 2020, along with the percent of the total CVAP and total registered voter populations that are people of color. The difference between these shares, indicated by the "Diff" column, is a measure of how underrepresented people of color are among registrants versus the eligible population; in other words, how

[^11]Table 15: States with Highest Unregistered POC Shares, 2020

much POC electoral power is weakened by low registration rates. Some states on the list are also found in Tables 16 and 15: California, Texas, Arizona, and New Mexico. However, these states are joined by places with relatively large NAM populations that are hampered by low registration rates, including Nevada and New Jersey.

## 6 Takeaways and Next Steps

In this report, we present an initial look at population and participation trends for the diverse, multi-group coalition known as the New American Majority (NAM). Using various data sources, we identify a large, growing NAM population that has the potential to shape

Table 17: States with Largest Difference between POC Share of CVAP and POC Share of Registrants, 2020

|  | CVAP | \% of CVAP | Registered | \% of Registered | Diff |

politics in many states going forward, but is hampered by relatively low rates of voter turnout. Several states that have relatively high shares of the NAM today are not poised to have as substantial NAM growth as, e.g., New England states. However, at the substate level we do see that NAM growth in suburban counties, driven by increases in the Black, Latinx, and AAPI populations, is occurring in many states and urban areas where voters of color already play a significant role in shaping politics.

Next steps for this project and related efforts point in three directions. First, it is important to further vet sources of data regarding voter turnout. We find that commonly-used data sources like the Current Population Survey have pitfalls that suggest voter file data may be a superior option. Second, county and other sub-state analyses may provide additional information about where voter file lists are accurate and how a young, diverse, geographically mobile NAM population can be best measured. Finally, our research suggests that areas of NAM population growth are changing rapidly, necessitating a closer, neighborhoodlevel look to determine if pre-COVID pandemic trends are still valid and how neighborhood change intersects with electoral participation. While the analyses we provide are in some ways tentative, it is clear that the NAM population is too critical to our future to leave these questions unanswered.

Note: * indicates states where registration data is especially unreliable. In Utah, over $10 \%$ of voters in 2020 opted out of having their information available in the public voter file. North Dakota does not have a permanent voter registration list.

    ${ }^{13} 10$ southern states currently request information about race/ethnicity when a person registers to vote. This information is often used to calibrate race modeling procedures. See, e.g., Fraga, Bernard L. (2018) The Turnout Gap: Race, Ethnicity, and Political Inequality in a Diversifying America. New York: Cambridge University Press.

[^3]:    ${ }^{15}$ There are two primary reasons why we focus on the citizen voting-age population (CVAP). First, unlike relying on the total adult population or total population, restricting the analysis to individuals who are adult citizens better reflects the pool of potential voters in state and federal elections. Second, while including some individuals who are ineligible to vote due to, e.g. felon disenfranchisement, data on the CVAP is more easily accessible and less subject to researcher interpretations of residency requirements, voting rights restoration procedures, and other state-level variation in eligibility restrictions.

[^5]:    ${ }^{19}$ We do not use the cohort-component approach given the lack of data on NAM-constituent intersections by birth cohort. See https://www.census.gov/programs-surveys/popproj/about.html Importantly, the cohortcomponent technique likely yields slightly more accurate estimates, but requires numerous assumptions about changing economic trends and comes at the expense of the subgroup granularity necessary to estimate the entire NAM.

    ${ }^{29}$ Importantly, the Census Bureau's PEP estimates use a cohort-component approach to modeling this change (See section 2.1 for more details). Therefore, our models reflect the cohort compositional change estimated over a 10 year period, and carry this forward to the subsequent 10 year period.
    ${ }^{30}$ The code to implement the national-level forecasts is located at: Census_Data/Data_Processing/us_processing.R. State and county forecasting code may be found in state_processing.R and county_processing.R, respectively.
